Ramesh Hariharan Mahler Measure

(日)

프 / 프

The Setting

• A polynomial f(x) with integral coefficients.

- We want a measure *M*(*f*) : *f*− > *R* of complexity which is related to (upper and lower bounded within some factors) the norm of *f* (which norm?).
- And which is multiplicative, i.e., M(fg) = M(f)M(g)

< □ > < 同 > < 三 > <

- Use a norm (0,1,2 or ∞) itself as the measure? Why doesn't this work.
- The multiplicative property requires that the measure be somehow related to a product of roots.
- Any integer polynomial with degree *d* has *d* (possibly complex and repeated) roots. Why?
- The product of all roots (or their moduli) is not an option. Why?

- Use a norm (0,1,2 or ∞) itself as the measure? Why doesn't this work.

$$f(x) = \sum_{0}^{d} a_k x^k = a_d \Pi_1^d (x - \alpha_i)$$

- *M*(*f*) = |*a_d*|Π_{*i*} max{1, |*α_i*|} where *α_i*'s are roots of *f* and *a_d* is the coefficient of *x^d*.
- So effectively leading term into product of roots outside the unit circle.
- Clearly multiplicative.
